Lecture 7

# **Orthogonal Projections**

DSC 40A, Spring 2024

#### Announcements

- Homework 3 is due on Saturday, April 27th.
  - Still try to finish it relatively early, since we won't have office hours on Saturday.
- Homework 1 scores are available on Gradescope.
  - Regrade requests are due on Sunday.

# Agenda

- Spans and projections.
- Matrices.
- Spans and projections, revisited.
- Regression and linear algebra.

Answer at q.dsc40a.com

#### Remember, you can always ask questions at q.dsc40a.com!

If the direct link doesn't work, click the "S Lecture Questions" link in the top right corner of dsc40a.com.

# **Spans and projections**

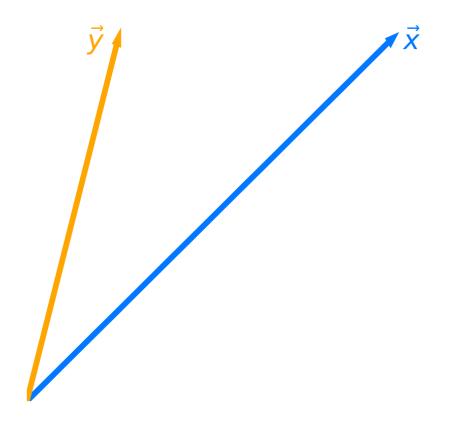

# Projecting onto a single vector

- Let  $\vec{x}$  and  $\vec{y}$  be two vectors in  $\mathbb{R}^n$ .
- The span of  $\vec{x}$  is the set of all vectors of the form:

#### $w\vec{x}$

where  $w \in \mathbb{R}$  is a scalar.

- Question: What vector in  $\operatorname{span}(\vec{x})$  is closest to  $\vec{y}$ ?
- The vector in  $\operatorname{span}(\vec{x})$  that is closest to  $\vec{y}$  is the \_\_\_\_\_ projection of  $\vec{y}$  onto  $\operatorname{span}(\vec{x})$ .

# **Projection error**

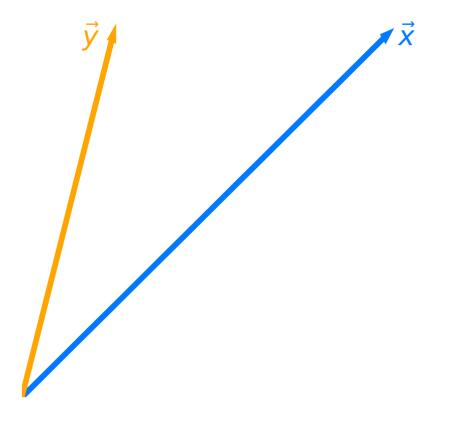

- Let  $\vec{e} = \vec{y} w\vec{x}$  be the projection error: that is, the vector that connects  $\vec{y}$ to span $(\vec{x})$ .
- Goal: Find the w that makes  $\vec{e}$  as short as possible.
  - That is, minimize:

#### $\|ec{e}\|$

• Equivalently, minimize:

 $\|ec{y} - wec{x}\|$ 

• Idea: To make  $\vec{e}$  has short as possible, it should be orthogonal to  $w\vec{x}$ .

## Minimizing projection error

- Goal: Find the w that makes  $\vec{e} = \vec{y} w\vec{x}$  as short as possible.
- Idea: To make  $\vec{e}$  as short as possible, it should be orthogonal to  $w\vec{x}$ .
- Can we prove that making  $\vec{e}$  orthogonal to  $w\vec{x}$  minimizes  $\|\vec{e}\|$ ?

# Minimizing projection error

- Goal: Find the w that makes  $\vec{e} = \vec{y} w\vec{x}$  as short as possible.
- Now we know that to minimize  $\|\vec{e}\|, \vec{e}$  must be orthogonal to  $w\vec{x}$ .
- Given this fact, how can we solve for *w*?

### **Orthogonal projection**

- Question: What vector in span $(\vec{x})$  is closest to  $\vec{y}$ ?
- **Answer**: It is the vector  $w^* \vec{x}$ , where:

$$w^* = rac{ec{x}\cdotec{y}}{ec{x}\cdotec{x}}$$

• Note that  $w^*$  is the solution to a minimization problem, specifically, this one:

$$\operatorname{error}(w) = \|ec{e}\| = \|ec{y} - wec{z}\|$$

• We call  $w^* \vec{x}$  the orthogonal projection of  $\vec{y}$  onto  $\operatorname{span}(\vec{x})$ .

• Think of  $w^* \vec{x}$  as the "shadow" of  $\vec{y}$ .

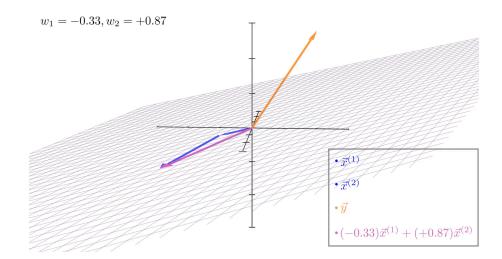

# Exercise

Let 
$$ec{a} = egin{bmatrix} 5 \\ 2 \end{bmatrix}$$
 and  $ec{b} = egin{bmatrix} -1 \\ 9 \end{bmatrix}$ .

What is the orthogonal projection of  $\vec{a}$  onto  $\operatorname{span}(\vec{b})$ ? Your answer should be of the form  $w^*\vec{b}$ , where  $w^*$  is a scalar.

#### Moving to multiple dimensions

- Let's now consider three vectors,  $\vec{y}$ ,  $\vec{x}^{(1)}$ , and  $\vec{x}^{(2)}$ , all in  $\mathbb{R}^n$ .
- Question: What vector in  $\operatorname{span}(\vec{x}^{(1)}, \vec{x}^{(2)})$  is closest to  $\vec{y}$ ?
  - Vectors in  $\operatorname{span}(\vec{x}^{(1)}, \vec{x}^{(2)})$  are of the form  $w_1 \vec{x}^{(1)} + w_2 \vec{x}^{(2)}$ , where  $w_1, w_2 \in \mathbb{R}$  are scalars.
- Before trying to answer, let's watch this animation that Jack, one of our tutors, made.

- Question: What vector in  $\operatorname{span}(\vec{x}^{(1)}, \vec{x}^{(2)})$  is closest to  $\vec{y}$ ?
  - That is, what vector minimizes  $\|\vec{e}\|$ , where:

$$ec{e} = ec{y} - w_1 ec{x}^{(1)} - w_2 ec{x}^{(2)}$$

- Answer: It's the vector such that  $w_1 \vec{x}^{(1)} + w_2 \vec{x}^{(2)}$  is orthogonal to  $\vec{e}$ .
- Issue: Solving for  $w_1$  and  $w_2$  in the following equation is difficult:

$$\left(w_1 ec{x}^{(1)} + w_2 ec{x}^{(2)}
ight) \cdot \underbrace{\left(ec{y} - w_1 ec{x}^{(1)} - w_2 ec{x}^{(2)}
ight)}_{ec{e}} = 0$$

• It's hard for us to solve for  $w_1$  and  $w_2$  in:

$$ig(w_1ec{x}^{(1)}+w_2ec{x}^{(2)}ig)\cdot \underbrace{ig(ec{y}-w_1ec{x}^{(1)}-w_2ec{x}^{(2)}ig)}_{ec{e}}=0$$

• Observation: All we really need is for  $\vec{x}^{(1)}$  and  $\vec{x}^{(2)}$  to individually be orthogonal to  $\vec{e}$ .

• That is, it's sufficient for  $\vec{e}$  to be orthogonal to the spanning vectors themselves.

• If  $ec{x}^{(1)} \cdot ec{e} = 0$  and  $ec{x}^{(2)} \cdot ec{e} = 0$ , then:

- Question: What vector in  $\operatorname{span}(\vec{x}^{(1)}, \vec{x}^{(2)})$  is closest to  $\vec{y}$ ?
- Answer: It's the vector such that  $w_1 \vec{x}^{(1)} + w_2 \vec{x}^{(2)}$  is orthogonal to  $\vec{e} = \vec{y} w_1 \vec{x}^{(1)} w_2 \vec{x}^{(2)}$ .
- Equivalently, it's the vector such that  $\vec{x}^{(1)}$  and  $\vec{x}^{(2)}$  are both orthogonal to  $\vec{e}$ :

$$egin{aligned} ec{x}^{(1)} \cdot \left(ec{y} - w_1 ec{x}^{(1)} - w_2 ec{x}^{(2)}
ight) &= 0 \ ec{x}^{(2)} \cdot \left(ec{y} - w_1 ec{x}^{(1)} - w_2 ec{x}^{(2)}
ight) &= 0 \ ec{e} &ec{e} &ec{e}$$

• This is a system of two equations, two unknowns ( $w_1$  and  $w_2$ ), but it still looks difficult to solve.

#### Now what?

• We're looking for the scalars  $w_1$  and  $w_2$  that satisfy the following equations:

$$egin{aligned} ec{x}^{(1)} \cdot \left(ec{y} - w_1 ec{x}^{(1)} - w_2 ec{x}^{(2)}
ight) &= 0 \ ec{x}^{(2)} \cdot \left(ec{y} - w_1 ec{x}^{(1)} - w_2 ec{x}^{(2)}
ight) &= 0 \ ec{e} &ec{e} &ec{e}$$

- In this example, we just have two spanning vectors,  $\vec{x}^{(1)}$  and  $\vec{x}^{(2)}$ .
- If we had any more, this system of equations would get extremely messy, extremely quickly.
- Idea: Rewrite the above system of equations as a single equation, involving matrixvector products.

# Matrices

## **Matrices**

- An n imes d matrix is a table of numbers with n rows and d columns.
- We use upper-case letters to denote matrices.

$$A = egin{bmatrix} 2 & 5 & 8 \ -1 & 5 & -3 \end{bmatrix}$$

- Since A has two rows and three columns, we say  $A \in \mathbb{R}^{2 imes 3}.$
- Key idea: Think of a matrix as several column vectors, stacked next to each other.

#### Matrix addition and scalar multiplication

- We can add two matrices only if they have the same dimensions.
- Addition occurs elementwise:

$$egin{bmatrix} 2 & 5 & 8 \ -1 & 5 & -3 \end{bmatrix} + egin{bmatrix} 1 & 2 & 3 \ 0 & 1 & 2 \end{bmatrix} = egin{bmatrix} 3 & 7 & 11 \ -1 & 6 & -1 \end{bmatrix}$$

• Scalar multiplication occurs elementwise, too:

$$2\begin{bmatrix} 2 & 5 & 8 \\ -1 & 5 & -3 \end{bmatrix} = \begin{bmatrix} 4 & 10 & 16 \\ -2 & 10 & -6 \end{bmatrix}$$

#### Matrix-matrix multiplication

• Key idea: We can multiply matrices A and B if and only if:

 $\# ext{ columns in } A = \# ext{ rows in } B$ 

- If A is  $n \times d$  and B is  $d \times p$ , then AB is  $n \times p$ .
- Example: If A is as defined below, what is  $A^T A$ ?

$$A=egin{bmatrix}2&5&8\-1&5&-3\end{bmatrix}$$

#### Answer at q.dsc40a.com

Assume *A*, *B*, and *C* are all matrices. Select the **incorrect** statement below.

- A. A(B+C) = AB + AC.
- B. A(BC) = (AB)C.
- C. AB = BA.
- $D(A + B)^T = A^T + B^T$ .
- $\mathsf{E}_{\cdot}(AB)^T = B^T A^T$ .

#### Matrix-vector multiplication

• A vector  $ec{v} \in \mathbb{R}^n$  is a matrix with n rows and 1 column.

$$ec{v} = egin{bmatrix} v_1 \ v_2 \ dots \ v_n \end{bmatrix}$$

- Suppose  $A \in \mathbb{R}^{n imes d}$ .
  - $\circ~$  What must the dimensions of  $ec{v}$  be in order for the product  $Aec{v}$  to be valid?
  - $\circ~$  What must the dimensions of  $ec{v}$  be in order for the product  $ec{v}^TA$  to be valid?

#### One view of matrix-vector multiplication

- One way of thinking about the product  $A\vec{v}$  is that it is **the dot product of**  $\vec{v}$  **with every row of** A.
- Example: What is  $A\vec{v}$ ?

$$A = egin{bmatrix} 2 & 5 & 8 \ -1 & 5 & -3 \end{bmatrix} \qquad ec{v} = egin{bmatrix} 2 \ -1 \ -5 \end{bmatrix}$$

#### Another view of matrix-vector multiplication

- Another way of thinking about the product  $A\vec{v}$  is that it is a linear combination of the columns of A, using the weights in  $\vec{v}$ .
- Example: What is  $A\vec{v}$ ?

$$A = egin{bmatrix} 2 & 5 & 8 \ -1 & 5 & -3 \end{bmatrix} \qquad ec{v} = egin{bmatrix} 2 \ -1 \ -5 \end{bmatrix}$$

#### Matrix-vector products create linear combinations of columns!

• Key idea: It'll be very useful to think of the matrix-vector product  $A\vec{v}$  as a linear combination of the columns of A, using the weights in  $\vec{v}$ .

$$A = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1d} \\ a_{21} & a_{22} & \dots & a_{2d} \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \dots & a_{nd} \end{bmatrix} \qquad \vec{v} = \begin{bmatrix} v_1 \\ v_2 \\ \vdots \\ v_d \end{bmatrix}$$
$$\downarrow$$
$$A\vec{v} = v_1 \begin{bmatrix} a_{11} \\ a_{21} \\ \vdots \\ a_{n1} \end{bmatrix} + v_2 \begin{bmatrix} a_{12} \\ a_{22} \\ \vdots \\ a_{n2} \end{bmatrix} + \dots + v_d \begin{bmatrix} a_{1d} \\ a_{2d} \\ \vdots \\ a_{nd} \end{bmatrix}$$

# Spans and projections, revisited

#### Moving to multiple dimensions

- Let's now consider three vectors,  $\vec{y}$ ,  $\vec{x}^{(1)}$ , and  $\vec{x}^{(2)}$ , all in  $\mathbb{R}^n$ .
- Question: What vector in  $\operatorname{span}(\vec{x}^{(1)}, \vec{x}^{(2)})$  is closest to  $\vec{y}$ ?

• That is, what values of  $w_1$  and  $w_2$  minimize  $\|\vec{e}\| = \|\vec{y} - w_1\vec{x}^{(1)} - w_2\vec{x}^{(2)}\|$ ?

#### Matrix-vector products create linear combinations of columns!

$$ec{x}^{(1)} = egin{bmatrix} 2 \ 5 \ 3 \end{bmatrix} \qquad ec{x}^{(2)} = egin{bmatrix} -1 \ 0 \ 4 \end{bmatrix} \qquad ec{y} = egin{bmatrix} 1 \ 3 \ 9 \end{bmatrix}$$

• Combining  $\vec{x}^{(1)}$  and  $\vec{x}^{(2)}$  into a single matrix gives:

$$X = egin{bmatrix} | & | \ ec{x}^{(1)} & ec{x}^{(2)} \ | & | \end{bmatrix} = egin{bmatrix} ---- \ --- \ --- \ --- \end{bmatrix}$$

- Then, if  $ec{w} = \begin{bmatrix} w_1 \\ w_2 \end{bmatrix}$ , linear combinations of  $ec{x}^{(1)}$  and  $ec{x}^{(2)}$  can be written as  $Xec{w}$ .
- The span of the columns of X, or span(X), consists of all vectors that can be written in the form  $X\vec{w}$ .

$$X = egin{bmatrix} | & | \ ec{x}^{(1)} & ec{x}^{(2)} \ | & | \end{bmatrix} = egin{bmatrix} 2 & -1 \ 5 & 0 \ 3 & 4 \end{bmatrix} \qquad ec{y} = egin{bmatrix} 1 \ 3 \ 9 \end{bmatrix}$$

- Goal: Find the vector  $\vec{w} = \begin{bmatrix} w_1 & w_2 \end{bmatrix}^T$  such that  $\|\vec{e}\| = \|\vec{y} X\vec{w}\|$  is minimized.
- As we've seen,  $\vec{w}$  must be such that:

$$egin{aligned} ec{x}^{(1)} \cdot \left(ec{y} - w_1 ec{x}^{(1)} - w_2 ec{x}^{(2)}
ight) &= 0 \ ec{x}^{(2)} \cdot \left(ec{y} - w_1 ec{x}^{(1)} - w_2 ec{x}^{(2)}
ight) &= 0 \ ec{e} &ec{e} \end{aligned}$$

 How can we use our knowledge of matrices to rewrite this system of equations as a single equation? Simplifying the system of equations, using matrices

$$X = egin{bmatrix} ert \ e$$

Simplifying the system of equations, using matrices

$$X = \begin{bmatrix} | & | \\ \vec{x}^{(1)} & \vec{x}^{(2)} \\ | & | \end{bmatrix} = \begin{bmatrix} 2 & -1 \\ 5 & 0 \\ 3 & 4 \end{bmatrix} \qquad \vec{y} = \begin{bmatrix} 1 \\ 3 \\ 9 \end{bmatrix}$$

1.  $w_1 ec{x}^{(1)} + w_2 ec{x}^{(2)}$  can be written as  $X ec{w}$ , so  $ec{e} = ec{y} - X ec{w}$ .

2. The condition that  $\vec{e}$  must be orthogonal to each column of X is equivalent to condition that  $X^T \vec{e} = 0$ .

#### The normal equations

$$X = egin{bmatrix} | & | \ ec{x}^{(1)} & ec{x}^{(2)} \ | & | \end{bmatrix} = egin{bmatrix} 2 & -1 \ 5 & 0 \ 3 & 4 \end{bmatrix} \qquad ec{y} = egin{bmatrix} 1 \ 3 \ 9 \end{bmatrix}$$

- Goal: Find the vector  $\vec{w} = \begin{bmatrix} w_1 & w_2 \end{bmatrix}^T$  such that  $\|\vec{e}\| = \|\vec{y} X\vec{w}\|$  is minimized.
- We now know that it is the vector  $\vec{w}^*$  such that:

$$egin{aligned} X^Tec{e} &= 0\ X^T(ec{y} - Xec{w}^*) &= 0\ X^Tec{y} - X^TXec{w}^* &= 0\ &\Longrightarrow X^TXec{w}^* &= X^Tec{y} \end{aligned}$$

• The last statement is referred to as the normal equations.

#### The general solution to the normal equation

 $X \in \mathbb{R}^{n imes d}$   $ec{y} \in \mathbb{R}^n$ 

- Goal, in general: Find the vector  $\vec{w} \in \mathbb{R}^d$  such that  $\|\vec{e}\| = \|\vec{y} X\vec{w}\|$  is minimized.
- We now know that it is the vector  $\vec{w}^*$  such that:

$$X^T \vec{e} = 0$$
  
 $\implies X^T X \vec{w}^* = X^T \vec{y}$ 

• Assuming  $X^T X$  is invertible, this is the vector:

$$ec{w}^* = (X^T X)^{-1} X^T ec{y}$$

- This is a big assumption, because it requires  $X^T X$  to be full rank.
- If  $X^T X$  is not full rank, then there are infinitely many solutions to the normal equations,  $X^T X \vec{w}^* = X^T \vec{y}$ .

#### What does it mean?

- Original question: What vector in  $\operatorname{span}(\vec{x}^{(1)}, \vec{x}^{(2)})$  is closest to  $\vec{y}$ ?
- Final answer: It is the vector  $X\vec{w}^*$ , where:

$$ec{w}^* = (X^T X)^{-1} X^T ec{y}$$

• Revisiting our example:

$$X = \begin{bmatrix} | & | \\ \vec{x}^{(1)} & \vec{x}^{(2)} \\ | & | \end{bmatrix} = \begin{bmatrix} 2 & -1 \\ 5 & 0 \\ 3 & 4 \end{bmatrix} \qquad \vec{y} = \begin{bmatrix} 1 \\ 3 \\ 9 \end{bmatrix}$$

- Using a computer gives us  $\vec{w}^* = (X^T X)^{-1} X^T \vec{y} \approx \begin{bmatrix} 0.7289 \\ 1.6300 \end{bmatrix}$ .
- So, the vector in  $\operatorname{span}(\vec{x}^{(1)},\vec{x}^{(2)})$  closest to  $\vec{y}$  is  $0.7289\vec{x}^{(1)}+1.6300\vec{x}^{(2)}$ .

#### An optimization problem, solved

- We just used linear algebra to solve an **optimization problem**.
- Specifically, the function we minimized is:

$$\operatorname{error}(\vec{w}) = \|\vec{y} - X\vec{w}\|$$

• This is a function whose input is a vector,  $\vec{w}$ , and whose output is a scalar!

• The input,  $ec{w}^*$ , to  $\mathrm{error}(ec{w})$  that minimizes it is:

 $ec{w}^* = (X^T X)^{-1} X^T ec{y}$ 

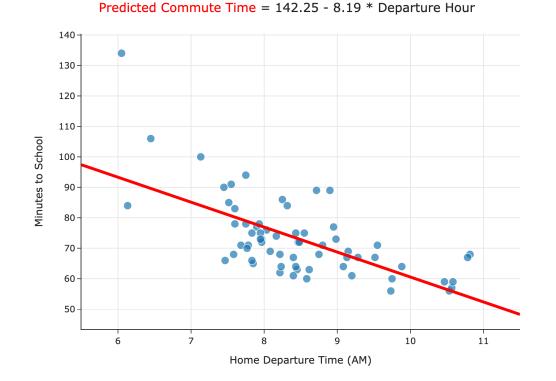

• We're going to use this frequently!

# **Regression and linear algebra**

#### Wait... why do we need linear algebra?

- Soon, we'll want to make predictions using more than one feature.
  - Example: Predicting commute times using departure hour and temperature.
- Thinking about linear regression in terms of **matrices and vectors** will allow us to find hypothesis functions that:
  - Use multiple features (input variables).
  - $\circ\,$  Are non-linear in the features, e.g.  $H(x)=w_0+w_1x+w_2x^2.$
- Let's see if we can put what we've just learned to use.

#### Simple linear regression, revisited

- Model:  $H(x) = w_0 + w_1 x$ .
- Loss function:  $(y_i H(x_i))^2$ .
- To find  $w_0^*$  and  $w_1^*$ , we minimized empirical risk, i.e. average loss:

$$R_{ ext{sq}}(H) = rac{1}{n}\sum_{i=1}^n \left(y_i - H(x_i)
ight)^2$$

- Observation:  $R_{
m sq}(w_0,w_1)$  kind of looks like the formula for the norm of a vector,

$$\|ec{v}\| = \sqrt{v_1^2 + v_2^2 + \ldots + v_n^2}.$$

#### **Regression and linear algebra**

Let's define a few new terms:

- The observation vector is the vector  $\vec{y} \in \mathbb{R}^n$ . This is the vector of observed "actual values".
- The **hypothesis vector** is the vector  $\vec{h} \in \mathbb{R}^n$  with components  $H(x_i)$ . This is the vector of predicted values.
- The error vector is the vector  $\vec{e} \in \mathbb{R}^n$  with components:

$$e_i = y_i - H(x_i)$$

## Example

Consider 
$$H(x) = 2 + \frac{1}{2}x$$
.  
 $\vec{y} = \vec{h} =$   
 $\vec{e} = \vec{y} - \vec{h} =$   
 $R_{sq}(H) = \frac{1}{n} \sum_{i=1}^{n} (y_i - H(x_i))^2$   
 $=$ 

 $ec{h} =$ 

#### **Regression and linear algebra**

Let's define a few new terms:

- The observation vector is the vector  $\vec{y} \in \mathbb{R}^n$ . This is the vector of observed "actual values".
- The **hypothesis vector** is the vector  $\vec{h} \in \mathbb{R}^n$  with components  $H(x_i)$ . This is the vector of predicted values.
- The error vector is the vector  $\vec{e} \in \mathbb{R}^n$  with components:

$$e_i = y_i - H(x_i)$$

• Key idea: We can rewrite the mean squared error of *H* as:

$$R_{
m sq}(H) = rac{1}{n} \sum_{i=1}^n \left( oldsymbol{y}_i - H(x_i) 
ight)^2 = rac{1}{n} \|oldsymbol{ec{e}}\|^2 = rac{1}{n} \|oldsymbol{ec{y}} - oldsymbol{ec{h}}\|^2$$

#### The hypothesis vector

- The **hypothesis vector** is the vector  $\vec{h} \in \mathbb{R}^n$  with components  $H(x_i)$ . This is the vector of predicted values.
- For the linear hypothesis function  $H(x) = w_0 + w_1 x$ , the hypothesis vector can be written:

$$ec{h} = egin{bmatrix} w_0 + w_1 x_1 \ w_0 + w_1 x_2 \ dots \ dots \ w_0 + w_1 x_n \end{bmatrix} = \ dots \ w_0 + w_1 x_n \end{bmatrix}$$

#### **Rewriting the mean squared error**

• Define the **design matrix**  $X \in \mathbb{R}^{n \times 2}$  as:

$$X = egin{bmatrix} 1 & x_1 \ 1 & x_2 \ dots & dots \ 1 & dots \ 1 & x_n \end{bmatrix}$$

- Define the parameter vector  $ec w \in \mathbb{R}^2$  to be  $ec w = igg| igwedge w_1 igg|.$
- Then,  $\vec{h} = X\vec{w}$ , so the mean squared error becomes:

$$R_{ ext{sq}}(H) = rac{1}{n} \|ec{m{y}} - ec{m{h}}\|^2 \implies egin{array}{c} R_{ ext{sq}}(ec{w}) = rac{1}{n} \|ec{m{y}} - m{X}ec{w}\|^2 \end{bmatrix}$$

#### What's next?

• To find the optimal model parameters for simple linear regression,  $w_0^*$  and  $w_1^*$ , we previously minimized:

$$R_{ ext{sq}}(w_0,w_1) = rac{1}{n}\sum_{i=1}^n (oldsymbol{y_i} - (w_0 + w_1oldsymbol{x_i}))^2$$

• Now that we've reframed the simple linear regression problem in terms of linear algebra, we can find  $w_0^*$  and  $w_1^*$  by minimizing:

$$egin{aligned} R_{ ext{sq}}(ec{w}) &= rac{1}{n} \|ec{y} - oldsymbol{X}ec{w}\|^2 \end{aligned}$$

• We've already solved this problem! Assuming  $X^T X$  is invertible, the best  $\vec{w}$  is:

$$ec{w}^* = (X^T X)^{-1} X^T ec{y}$$
